

Intro to Efficient Programming

Mikolaj Krzewicki¹ Patrick Huhn³ Sandro Wenzel²

¹FIAS/University of Frankfurt

²CERN

³University of Frankfurt

HGS-HIRe power week

Limburg

June 2019

Lecture I

Introduction

Who we are

Mikolaj Krzewicki

- ▶ in ALICE since 2007
- ▶ ALICE High Level Trigger / ALICE O2
- ▶ Software validation
- ▶ TPC calibration
- ▶ Analysis (correlations and flow)

Patrick Huhn

- ▶ in ALICE since 2014
- ▶ PhD student since 2017
- ▶ former participant of this power week
- ▶ Analysis (charged particle R_{AA})

Sandro Wenzel

- ▶ at CERN since 2012; in ALICE since 2015
- ▶ Detector Simulation
- ▶ Previous experience in various computing activities (PhD: Quantum Monte Carlo; The Blue Brain Project)

Credits

Material of this course building on previous courses given by Jens Wiechula, David Rohr, Matthias Richter and Jochen Klein.

Outline / Goals of the week

Software development / computing in high energy physics is ubiquitous and essential knowledge. This week should help you to ...

- ▶ Be able to come up with efficient algorithms in C++ implementing software solutions to problems in (particle) physics.
- ▶ Be able to use ROOT as a library and to look into data using ROOT
- ▶ Be able to decompose problem into small pieces, structure code and work on software projects incrementally
- ▶ Understand tools and practices in the software development process
- ▶ Know about modern C++11 features and few optimization strategies
- ▶ Know about easy parallelism options and SIMD

Introduction

There are many aspects of *efficiency*

- ▶ Coding concepts
- ▶ Tools
- ▶ Fast development (prototyping)
- ▶ Fast code execution (optimization)
- ▶ Small memory imprint
- ▶ Code design
- ▶ Code flexibility / configurability
- ▶ ...

Programme

What we want to cover:

- ▶ Modern C++ features and concepts (C++11, C++14, ...)
- ▶ Tools
 - ▶ gcc
 - ▶ (c)make
 - ▶ git
 - ▶ doxygen
 - ▶ gdb
 - ▶ profilers:
valgrind,
perf, ...
- ▶ Methods
 - ▶ object orientation, templates
 - ▶ libraries
- ▶ Algorithms
- ▶ Parallelisation
- ▶ SIMD vectorisation

Outlook Programme 2

What we can't cover here but intend to do in part 2:

- ▶ GP-GPU
- ▶ Parallelization in more depth
- ▶ distributed computing and messaging
- ▶ ...

Course format

There will be some lectures but focus will be on practical side!

- ▶ Lot's of do-it yourself exercises/examples
- ▶ A real coding project touch typical high energy physics subject
- ▶ Possibility to do code reviews / interaction with lecturers

link to dynamic plan

<https://tinyurl.com/hgspw1>

A small project

- ▶ small groups (up to 5 people)
- ▶ work shall be carried out over the whole week, presentation of results on Friday (20+5), code reviews in between
- ▶ we want you to
 - ▶ use the tools
 - ▶ try the methods
 - ▶ test the algorithmswhich are discussed during the meeting
- ▶ you should learn something
⇒ try and understand what you are doing

Computing I

- ▶ local servers (hostnames: power[1-4].power.week)
personal user accounts:
username: first letter of firstname + lastname,
initial password: pwLimburg
(reference environment, you can compare to your machine)
- ▶ Every groups gets assigned one server (please use it exclusively)
- ▶ separate network with WLAN access (or cable)
SSID: PowerWeek_01
pw: powerweek
- ▶ passwordless login
often it is convenient to login using ssh keys

```
ssh-keygen  
ssh-copy-id <you-user-id>@power[1-4]
```

Computing II

- ▶ examples and slides are provided via git

```
git clone https://github.com/hgspowerweek/powerweek1/  
cd powerweek1  
git pull
```

do the last step before every session and you will get the latest examples and slides

- ▶ Slides are directly in this folder as pdfs
- ▶ Examples are in the folder *examples*

examples/bla

Lecture II

Introduction to code / document
management using git – absolute basics

Code repository

Why would you use a code repository?

- ▶ keep control over your changes
- ▶ keep a history of changes and go back to any previous state
- ▶ add logging messages to individual changes
- ▶ develop different topics in parallel
- ▶ keep a working version as a reference
- ▶ create releases for distribution of the code
- ▶ synchronize several developers

A code repository can serve as

- ▶ back-up solution
- ▶ communication medium
- ▶ team and product management tool

git - the stupid content tracker

- ▶ Developed by Linus Torvalds and others in 2005 for the Linux kernel community
- ▶ Nobody knows what git stands for at least one does not get a real answer.
- ▶ Instead of being stupid - see manpage - it's an extremely powerful scalable, distributed revision control system.

In contrast to other versioning systems (CVS, subversion),

- ▶ git allows to use the full functionality of a code repository locally
- ▶ can be distributed
- ▶ does not require a central server, but can be used with a server

git commands in a nutshell

Basic operations:

- ▶ `git init`
- ▶ `git clone`
- ▶ `git add` – add something to staging area
- ▶ `git commit` – commit staging area to local repository
- ▶ `git checkout <commit>` – retrieve certain state

Getting information

- ▶ `git log` – show commit history
- ▶ `git status`
- ▶ `git diff` – show differences (between commits)

Advanced commands

- ▶ `git stash`
- ▶ `git push` – publish repo somewhere else (some URL)
- ▶ `git pull` – sync/get changes from somewhere else (some URL)
- ▶ `git rebase/merge` – integrate someone elses changes; change history

git - the stupid content tracker

How is a git repository structured:

- ▶ **local copy** (tree) - those are your files.
 - ▶ **staging area** (intermediate store) - changes (diffs) staged for commit.
 - ▶ **local repository** - full repository containing all changes to all branches.
- Everybody has a full copy, there is no concept of a central repository - you still may declare some repository the central one.

git - One time (identity) setup

- ▶ `git config` Configure git or query configuration
- ▶ **Some essential setup:** Give yourself a git identity:

```
git config --global user.name "Foo Bar"  
git config --global user.email foo.bar@cern.ch
```

- ▶ `git config -l` will show you the whole configuration including your identity
- ▶ configuration is stored in a file `${HOME}/gitconfig` which can also be edited

git - Creating and cloning repositories

Creating an initial repository:

```
mkdir -p ~/src/project
cd ~/src/project
git init
Initialized empty Git repository in ~/src/project/.git
```

Cloning a repository:

```
git clone power1:/data/PowerWeek
Cloning into 'PowerWeek'...
Password:
remote: Counting objects: 6, done.
remote: Compressing objects: 100% (4/4), done.
remote: Total 6 (delta 1), reused 0 (delta 0)
Receiving objects: 100% (6/6), done.
Resolving deltas: 100% (1/1), done.
Checking connectivity... done
```

git - status of the local repository

Command: `git status`

```
richterm@power1 ~ git status
# On branch master
# Changes not staged for commit:
#   (use "git add <file>..." to update what will be committed)
#   (use "git checkout -- <file>..." to discard changes in working directory)
#
#       modified:   twoparticle.C
#
# Untracked files:
#   (use "git add <file>..." to include in what will be committed)
#
#       result.root
#       twoparticle_C.d
#       twoparticle_C.so
no changes added to commit (use "git add" and/or "git commit -a")
```

- ▶ information about the current branch
- ▶ files which are staged for commit
- ▶ tracked files with local changes
- ▶ untracked files (can be masked by `.gitignore`)

git - committing

Step 1: `git add` mark changes to be committed

```
richterm@power1 ~/src/example_01 $ git add twoparticle.C
richterm@power1 ~/src/example_01 $ git status
# On branch master
# Changes to be committed:
#   (use "git reset HEAD <file>..." to unstage)
#
#       modified:   twoparticle.C
#
# Untracked files:
#   (use "git add <file>..." to include in what will be committed)
#
#       result.root
#       twoparticle_C.d
#       twoparticle_C.so
```

git - committing

Step 2: `git commit` changes

```
richterm@power1 ~/src/example_01 git commit -m "initial version  
of particle class"
```

```
[master a56e827] initial version of particle class
```

Now it is locally committed, check the log

```
richterm@power1 ~/src/example_01 git log  
commit a56e8270fd6f3c99d4cdbcd0e45f287e1c71711  
Author: Matthias Richter <richterm@power1.power.week>  
Date: Tue Nov 26 11:51:09 2013 +0100
```

```
    initial version of particle class
```

```
commit ea2c328e7ac3e21c5546480dad1a55af4a0f5e35  
Author: Jochen Klein <jochen.klein@cern.ch>  
Date: Mon Nov 25 13:51:12 2013 +0100
```

```
    - initial commit of example
```

git commits; git checkout

- ▶ git organizes commits in a connected **tree** of nodes; A **git commit** adds a new node
- ▶ each node consists of
 - ▶ The actual changeset/diff to files
 - ▶ Metadata (author, ...)
 - ▶ A commit message
 - ▶ A **SHA-256 hash digest** - This hash uniquely identifies the precise node and all its history!
- ▶ one can checkout specific nodes by using **git checkout <commit-sha>**
- ▶ pointer to last node – of main development line – is typically called **master**

The commit tree and branches

The git commit structure can be a tree. Pointers to leave nodes are called **branches**.

- ▶ The master branch is the main development line
- ▶ Other branches typically used for feature development in isolation (Feat1) or for releasing a certain stable version and patches (v1-patch)
- ▶ branches are started with `git checkout -b NewFeature` on the currently checked out commit
- ▶ one can switch between branches with `git checkout branchname`

```
$ git checkout -b v1-patch
$ git commit
$ git checkout master
$ git checkout -b feat1
$ git commit
$ git checkout master
$ git commit
```

nice online learning platform: <https://learngitbranching.js.org/?NODEMO>

Short intro to merging and rebasing

- ▶ **merging/rebasing** : operations on the tree to bring together 2 branches
- ▶ used to integrate commits from one branch into the other
- ▶ for example when feature is fully developed

`git merge feat1`

- ▶ tree (old commits) stays intact
- ▶ merge creates adds a special commit

`git rebase feat2`

- ▶ branches are linearized
- ▶ no new commit; but old commits rewritten

git - looking at the difference

Command: `git diff`

```
richterm@power1 ~/src/example_01 git diff twoparticle.C
diff --git a/twoparticle.C b/twoparticle.C
index fdca6ac..77d77c5 100644
--- a/twoparticle.C
+++ b/twoparticle.C
@@ -1,7 +1,7 @@
    // a simple macro with surprises for the purpose of training usage of valgrind a

    // include header files for the purpose of compilation
-#ifndef __CINT__
+#if !defined(__CINT__) || defined(__MAKECINT__)
    #include "TParticle.h"
    #include "TSystem.h"
    #include "TH1.h"
```

- ▶ shows local differences in tracked files
- ▶ without arguments: for all tracked files
- ▶ can be used to show differences between revisions

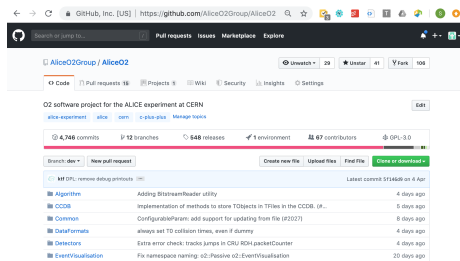

Distributed gits: push and pull

- ▶ A git repository can exist at various locations (or in multiple copies) at the same time (it's distributed); one speaks of local and remote repositories.
- ▶ the authoritative version of a git repository is often hosted on some web server (remote)
 - ▶ if you cloned from the remote it is called 'origin'
 - ▶ otherwise you can declare a remote repo with
`git remote add foo URL`
- ▶ Users synchronize local and remote repositories via git pull and git push commands.
 - ▶ `git pull [-rebase] foo` get all remote changes and apply locally
 - ▶ `git push foo` publish your own changes to the remote

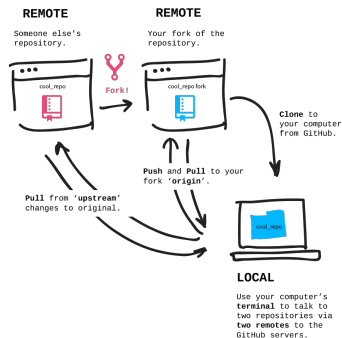

Github/Gitlab/Bitbucket

- ▶ many open source projects host git on platforms like Github, Gitlab or Bitbucket
- ▶ free git server and infrastructure
- ▶ collaborative code reviews
- ▶ integrations with other services
 - ▶ task tracking
 - ▶ continuous integration (CI) - automatic testing of new code and accepting only if good
 - ▶ documentation

Github/Gitlab/Bitbucket - workflow

- ▶ A typical workflow on those platforms uses 3 repositories
 - ▶ the authoritative repo (remote)
 - ▶ a fork (a user copy remote)
 - ▶ the local user repository
- ▶ Changes are integrated via push to fork and pull requests to real repo

git - Further reading

We found the following nice looking pages ... but there are tons other really

- ▶ <https://rogerdudler.github.io/git-guide/index.de.html>
- ▶ <https://try.github.io/> – resources to learn git;
- ▶ <https://www.atlassian.com/git/tutorials>
- ▶ <https://www.edureka.co/blog/git-tutorial/>
- ▶ `git help`

git - stash

You are in the middle of developing and get a request to fix something or update your clone

⇒ `stash` allows to save your current status

```
> git pull
# ... pull fails due to merge conflicts ...
> git stash save
> git pull
> git stash pop
```

git - checking logs revisited

tig; gitk; etc

Exercises

- ▶ Create a git repo; Do some add-commit cycles
- ▶ Play with branching merging:
 - ▶ locally
 - ▶ as an interactive game <https://learngitbranching.js.org/>
- ▶ Get familiar with github by forking or cloning the PowerWeek github repo <https://github.com/hgspowerweek/powerweek1>.
 - ▶ Look around
 - ▶ Contribute to the documentation of F.A.Q. section
- ▶ In order to contribute to an github repo, you need to create a github account
- ▶ For the coding project, we suggest to use gitlab.cern.ch in a private repository
 - ▶ needs CERN lightweight account account.cern.ch
 - ▶ keeps code private (also for future power weeks participants)
 - ▶ enables code review features

Lecture III

Code compilation

What is GCC

- ▶ Originally 'only' GNU C Compiler
- ▶ Release in March 1987 as the first **free** ANSI C optimizing compiler
- ▶ C++ support was added in December of that year
- ▶ Now, many other languages are supported as well, e.g. Objective-C, Objective-C++, Fortran (gfortran), Java (gcj), ...
- ▶ In addition, many different CPU architectures supported, e.g. Intel, ARM, Alpha, PowerPC, ...
- ▶ Today GCC stands for GNU Compiler Collection

Compilers

A compiler translates the human readable code into machine executable code

The main compilers of the GCC suite we are interested in are the GNU C and C++ compilers: gcc and g++

Brian Gough

<http://www.network-theory.co.uk/docs/gccintro/>

examples/gcc

First steps with g++

```
#include <iostream>
int main()
{
    std::cout << "hello world" << std::endl;
    return 0;
}
```

The hello world example above (hello_world.cpp) can be compiled using

```
g++ -Wall hello_world.cpp -o hello_world
```

-o specifies the name of the executable (default it is *a.out*)
-Wall turns on most commonly used compiler warning → **highly recommended to use**

To run the program simply type

```
./hello_world
```

⇒ Try it!

First steps with g++

```
#include <iostream>
int main()
{
    std::cout << "hello world" << std::endl;
    return 0;
}
```

The hello world example above (hello_world.cpp) can be compiled using

```
g++ -Wall hello_world.cpp -o hello_world
```

-o specifies the name of the executable (default it is *a.out*)
-Wall turns on most commonly used compiler warning → **highly recommended to use**

To run the program simply type

```
./hello_world
```

⇒ Try it!

First steps with g++

```
#include <iostream>
int main()
{
    std::cout << "hello world" << std::endl;
    return 0;
}
```

The hello world example above (hello_world.cpp) can be compiled using

```
g++ -Wall hello_world.cpp -o hello_world
```

-o specifies the name of the executable (default it is *a.out*)
-Wall turns on most commonly used compiler warning → **highly recommended to use**

To run the program simply type

```
./hello_world
```

⇒ Try it!

First steps with g++

```
#include <iostream>
int main()
{
    std::cout << "hello world" << std::endl;
    return 0;
}
```

The hello world example above (hello_world.cpp) can be compiled using

```
g++ -Wall hello_world.cpp -o hello_world
```

-o specifies the name of the executable (default it is *a.out*)

-Wall turns on most commonly used compiler warning → **highly recommended to use**

To run the program simply type

```
./hello_world
```

⇒ Try it!

Splitting code

Often it is useful to split the code into separate logical files

- ▶ Enhances readability and maintenance
- ▶ Enables to compile code parts independently
 - ▶ Saves compilation time, not all code needs to be recompiled if somethings changes
- ▶ Allows to compile code using the functionality of other code without knowing the actual implementation

We split the `hello_world` example into three files:

- ▶ `main.cpp`
- ▶ `hello_fn.h`
- ▶ `hello_fn.cpp`

Splitting code

Often it is useful to split the code into separate logical files

- ▶ Enhances readability and maintenance
- ▶ Enables to compile code parts independently
 - ▶ Saves compilation time, not all code needs to be recompiled if somethings changes
- ▶ Allows to compile code using the functionality of other code without knowing the actual implementation

We split the `hello_world` example into three files:

- ▶ `main.cpp`
- ▶ `hello_fn.h`
- ▶ `hello_fn.cpp`

Splitting code - example

main.cpp

```
#include "hello_fn.h"
int main()
{
    hello("world");
    return 0;
}
```

hello_fn.h

```
void hello(const char* to);
```

hello_fn.cpp

```
#include <iostream>
void hello(const char* to)
{
    // function to print hello to someone on the command line
    std::cout << "Hello " << to << std::endl;
}
```

Splitting code - header files

- ▶ Separate the *declaration* of classes / functions from the actual *implementation*
- ▶ The declaration is given in the *header file* ending on `.h`
- ▶ When using external code in an own class, during compilation only the declaration is needed
- ▶ A declaration should not be included several times (compilation time), this is handled by a pre-compiler directive (*header guard*)

```
#ifndef MYCODE_H
#define MYCODE_H
void myfunction(int x, float y);
#endif
```

Compile multiple source files

To compile the code run

```
g++ -Wall main.cpp hello_fn.cpp -o hello_world
```

⇒ Try it!

Not won too much, still all code is compiled all the time

- ▶ compile parts of the code into separate *object files*
- ▶ *link* the *object files* to the executable

Compile multiple source files

To compile the code run

```
g++ -Wall main.cpp hello_fn.cpp -o hello_world
```

⇒ Try it!

Not won too much, still all code is compiled all the time

- ▶ compile parts of the code into separate *object files*
- ▶ *link* the *object files* to the executable

Creating object files

We create one *object file* per input file:

```
g++ -Wall -c main.cpp hello_fn.cpp
```

- ▶ `-c` tells the compiler to create an object
- ▶ object files are machine code, but not yet executable

Produces the object files *main.o* and *hello_fn.o*

This can also be run separately for each file

```
g++ -Wall -c main.cpp  
g++ -Wall -c hello_fn.cpp
```

⇒ Try it!

Creating object files

We create one *object file* per input file:

```
g++ -Wall -c main.cpp hello_fn.cpp
```

- ▶ `-c` tells the compiler to create an object
- ▶ object files are machine code, but not yet executable

Produces the object files *main.o* and *hello_fn.o*

This can also be run separately for each file

```
g++ -Wall -c main.cpp  
g++ -Wall -c hello_fn.cpp
```

⇒ Try it!

Linking objects to an executable

Now the objects can be *linked* together to the executable:

```
g++ main.o hello_fn.o -o hello_world
```

NOTE:

The code is already compiled → You don't need warning options

⇒ Try it!

- ▶ Modify something in one of the files (e.g. world → moon in main.cpp)
- ▶ Recompile only main.cpp
- ▶ Link all files to one executable

⇒ Try it!

Linking objects to an executable

Now the objects can be *linked* together to the executable:

```
g++ main.o hello_fn.o -o hello_world
```

NOTE:

The code is already compiled → You don't need warning options

⇒ Try it!

- ▶ Modify something in one of the files (e.g. world → moon in main.cpp)
- ▶ Recompile only main.cpp
- ▶ Link all files to one executable

⇒ Try it!

Makefiles

- ▶ The steps mentioned above can be automatized using the *make system*
- ▶ Define dependencies (e.g. the executable can only be built if all objects files are available)
- ▶ Only compiles code which changed

Documentation:

<https://www.gnu.org/software/make/manual/make.html>

Makefiles – An example

```
CXX      = /usr/bin/g++
CXXFLAGS = -Wall -Wextra -Wconversion -Wshadow -g
LDFLAGS  =

OBJ      = hello_fn.o main.o

split: $(OBJ)
        $(CXX) -o $@ $(OBJ) $(LDFLAGS)

main.o: main.cpp hello_fn.h
        $(CXX) -o $@ -c $< $(CXXFLAGS)

%.o: %.cpp %.h
        $(CXX) $(CXXFLAGS) -c $< -o $@

clean:
        @rm -f ${OBJ} split
```

Makefiles – Primer

Makefiles consist of rules that tell the make system what to do. A rule has the form:

```
target ... : prerequisites ...  
<tab> recipe  
<tab> ...  
<tab> ...
```

target is usually an output file name, prerequisites can be other targets or e.g. file names

NOTE: A recipe MUST be started with a `< tab >`

When the `make` command is called, it looks for a file called *Makefile* or *makefile* in the present directory and processes the first target (*default target*)

Makefiles – Primer

A few important automatic variables are defined in the `make` system:

- ▶ `$@` The target name
- ▶ `$<` The first prerequisite
- ▶ `$^` The names of all the prerequisites, with spaces between them

For more see <https://www.gnu.org/software/make/manual/make.html#Automatic-Variables>

⇒ Try it!

CMake - introduction

- ▶ treatment of dependencies and automatic re-compilation covered by Makefiles and make
- ▶ manual maintenance of Makefiles can become tedious and error-prone
- ▶ configuration for specific setup of SDK and external dependencies covered by autotools suite or CMake

CMake - introduction

CMake is an open-source, cross-platform family of tools designed to build, test and package software.

- ▶ universal (toolchain agnostic) description of build flow in CMakeLists.txt
- ▶ automated creation of Makefiles depending on configuration options environment found
- ▶ automatic re-evaluation when needed
- ▶ possibly add testing and packaging steps

here: CMake with Makefiles

typical build layout

- ▶ separate build into different directories:
 - ▶ source: no generated files
 - ▶ build: generated files, object files, libraries, executables
possibly more than one with different build options
 - ▶ install: final files only
- ▶ test stage
- ▶ delivering/deploying stage

a minimal CMake project

```
cmake_minimum_required(VERSION 3.9)
project(MyPowerProject CXX)

add_executable(testExe test.cc)
```

- ▶ always specify minimum version of CMake (depending on the features you use)
 - ▶ declare project and language used
 - ▶ add targets (here just one executable)
-

example project:

```
examples/cmake_simple
```

a CMake run

```
cd <build directory>  
cmake <source directory>  
make -j$(nproc)
```

build happens in phases:

- ▶ configuration:
evaluation of CMakeLists.txt files, additional options, toolchain probing
- ▶ generation:
generation of build files (depending on selected generator)
- ▶ compilation:
actual build using Makefiles

libraries

```
add_library(power power.cc)
add_executable(main main.cc)
target_link_libraries(main power)
```

- ▶ add target for library and source files needed to build it
- ▶ link executable against library
- ▶ include directories are propagated to the targets using the library

using lists

...

```
set(SOURCES s1.cc s2.cc s3.cc)
add_library(s ${SOURCES})

set(EXECUTABLES e1 e2 e3)
foreach(EXE ${EXECUTABLES})
    add_executable(${EXE} ${EXE}.cc)
    target_link_libraries(${EXE} power)
endforeach()
```

- ▶ define lists that can be reused
- ▶ avoid overly repetitive code

ROOT integration

...

```
find_package(ROOT)
include(${ROOT_USE_FILE})
if(ROOT_FOUND)
    message(STATUS "Using ROOT: ${ROOT_VERSION} <${ROOT_CONFIG}>")
    target_compile_definitions(power PUBLIC "-DUSE_ROOT")
    target_include_directories(power PRIVATE ${ROOT_INCLUDE_DIRS})
    target_include_directories(power PRIVATE .)
    ROOT_GENERATE_DICTIONARY(G__Power ${CMAKE_CURRENT_SOURCE_DIR}/power.h LINKDEF Lin
    target_sources(power PRIVATE power_rooted.cc G__Power)
    target_link_libraries(power ROOT::Core ROOT::Gui ROOT::Tree)
endif(ROOT_FOUND)
```

- ▶ ROOT comes with additional tools to build dictionaries

warnings and errors

```
message("something important")
message(STATUS "just a status message")
message(WARNING "something's fishy here")
message(ERROR "this is plain wrong")
message(FATAL_ERROR "this is too wrong, I rather die ...")
```

- ▶ use messages to check on your build, don't be blind on what is happening

language options

...

```
set(CMAKE_CXX_STANDARD 14)
set(CMAKE_CXX_STANDARD_REQUIRED ON)
message(STATUS "Using C++${CMAKE_CXX_STANDARD}")

enable_language(CUDA)
```

- ▶ compiler-agnostic settings of language standard
N.B.: you can also request specific language features
- ▶ enabling of additional programming languages

build types and compiler options

```
set(CMAKE_CXX_FLAGS_DEBUG "-O0 -ggdb -DDEBUG -D__DEBUG")
set(CMAKE_CXX_FLAGS_RELWITHDEBINFO "${CMAKE_CXX_FLAGS_RELEASE} -ggdb")
set(CMAKE_CXX_FLAGS_RELEASE "-O3 -march=native -ftree-vectorize -ffast-math -DNODEBUG")
message(STATUS "Using CXX flags for ${CMAKE_BUILD_TYPE}: ${CMAKE_CXX_FLAGS_${CMAKE_BUILD_TYPE}}")
```

- ▶ compiler options/flags are controlled by build types
- ▶ can be changed separately for different build types
- ▶ don't put target-specific stuff here

```
cmake -DCMAKE_BUILD_TYPE=DEBUG <source> <dir>
```

default build type

```
# by default build optimized code with debug symbols
if(NOT CMAKE_BUILD_TYPE AND NOT CMAKE_CONFIGURATION_TYPES)
  set(CMAKE_BUILD_TYPE RELWITHDEBINFO)
endif()

set(CMAKE_ALLOWED_BUILD_TYPES DEBUG RELEASE RELWITHDEBINFO)
if(NOT CMAKE_BUILD_TYPE IN_LIST CMAKE_ALLOWED_BUILD_TYPES)
  message(FATAL_ERROR "Invalid build type ${CMAKE_BUILD_TYPE}. Use one of: ${CMAKE_
```

- explicit control over default build type

install

```
install(TARGETS main power  
        LIBRARY DESTINATION lib  
        RUNTIME DESTINATION bin  
)
```

- ▶ this should install only the final build products
- ▶ try and adhere to conventions about installation paths

some more involved stuff

- ▶ nested projects
- ▶ tests

nested projects

```
add_subdirectory(sub1)
add_subdirectory(sub2)
```

- ▶ include sub-projects in sub-directories, hierarchical layout
- ▶ sub-directories can contain project, this allows to build the sub-project independently
- ▶ different directories:
 - ▶ CMAKE_SOURCE_DIRECTORY: directory from which cmake was run
 - ▶ CMAKE_PROJECT_SOURCE_DIRECTORY: (sub-)project directory
 - ▶ CMAKE_CURRENT_SOURCE_DIRECTORY: current directory in source tree

CTest

- ▶ you can add tests which can be run programatically

```
enable_testing()  
  
add_test(NAME MyPowerTest COMMAND echo done)
```

```
ctest
```

You can also run this using the *make* process by

```
make test
```

summary

- ▶ surely not an extensive coverage of CMake, but it should get you started
- ▶ extensive documentation on project pages but not always good explanation of the underlying concepts

Lecture IV

Project

The problem

- ▶ consider an experiment to measure the X particle
- ▶ a renowned theorist told us some expectations:
 - ▶ decay to three charged pions
 - ▶ mass 50 – 100 GeV, known lifetime $c\tau = 0.5$ mm
 - ▶ production flat in η and $\propto p_T^{-5}$
 - ▶ in every n -th event (poisson around that mean), n most probably 5
- ▶ available detector covers $|\eta| < 2$ and full azimuth, provides one point at $R = 5$ cm with $\sigma = 0.1$ mm in z and $r\varphi$ direction, θ with a resolution of 1 degree and p_T with a resolution of $\Delta p_T / p_T = 0.5 \text{ \%} / (\text{GeV}/c) \cdot p_T$,
- ▶ on average 10 (poisson with mean 10) other primary particles (pions) produced, flat in η and $\propto p_T^{-8}$
exploit the known lifetime
- ▶ find a way to prove (or falsify) the existence of the X, which properties can be measured

Your task

Write the code to

- ▶ simulate the production of the X particle and its decay according to the specified properties
- ▶ simulate background particles produced in association with X
- ▶ smear the measured track properties (\vec{x} , p_T , η) (fast detector simulation)
- ▶ reconstruct the X particle
- ▶ analyze the performance of the reconstruction
- ▶ develop clever cuts on the analysis level

**Simulation, smearing, reconstruction, and analysis
should be kept separated!**

Some thoughts

- ▶ IO is usually quite slow, but might be important, optionally, for debugging purposes \Rightarrow use root trees
- ▶ simulation writes information to memory structure(s)
what information needed? how structured?
- ▶ smearing runs on these data / tree input
modify? copy? extend? file structure?
- ▶ reconstruction runs on these in memory structure(s) / tree input
what information is needed? what is produced?
- ▶ analysis runs on these in memory structure(s) / tree input
what information is needed?
- ▶ for specific problems (e.g. three-body decay) you might want to use external libraries (ROOT – e.g. TGenPhaseSpace)

You are free to do what you want.

Details

- ▶ Primary particles are created at the origin (exact position, no smearing).
- ▶ All spectra are flat in η and follow a power law in p_T , cut off at 100 MeV.
- ▶ The resolution of the tracking layers is $\sigma = 1$ mm in z and in $r\varphi$ direction (Gaussian). There is no error in r .
- ▶ The detector has full acceptance, every particle crossing a layer produces exactly one hit.
- ▶ For generating the hits, assume perfectly cylindrical detector layers.
- ▶ Mass of particles: X: 50 – 100 GeV
- ▶ Lifetime of particles: X: $c\tau = 0.5$ mm
- ▶ The mean number of background particles is $dN/d\eta = 2.5$, the mean number of X particles is $dN/d\eta = 0.25$ (Poissonian Distribution).
- ▶ The p_T spectrum of the X is proportional to p_T^{-5} , the p_T spectrum of the background is proportional to p_T^{-8} .

Lecture V

Object-oriented programming

Why object-oriented programming?

- ▶ paradigms:
 - ▶ machine operations (assembler)
 - ▶ functional formulation (Lisp, Lua, ...)
 - ▶ procedural languages (Fortran, C)
 - ▶ object-oriented (C++, Java, ...)
- ▶ problems before object-oriented programming:
 - ▶ inter-dependencies
 - ▶ name clashes
 - ▶ change of internal representations difficult
- ▶ solution:
 - ▶ encapsulate data and methods to access it
 - ▶ make it reusable without knowing the internal details
 - ▶ C with objects \rightsquigarrow C++

Objects

- ▶ user-defined type,
on equal footing with language types
- ▶ aggregate of
 - ▶ member variables (data)
 - ▶ methods
 - ▶ access policies
- ▶ use a object to describe a concept, e.g.
 - ▶ particle with properties
 - ▶ functor (map)
- ▶ C++ supports you to use objects,
it does not force you to write everything as a object!
- ▶ Object can be a *class* or a *struct*

Classes

Example

```
class particle {  
public:  
    particle() = default;  
    ~particle() = default;  
    particle(const particle &rhs) = default;  
    particle& operator=(const particle &rhs) = default;  
  
    float pt() const  
        { return sqrt(p[0]*p[0] + p[1]*p[1]); }  
  
protected:  
    std::array<float, 4> p{};  
};
```

- ▶ only a concept so far, no object yet

Instances

- ▶ you can create objects from a class (instances)

// on the stack

```
particle p1{};
```

// on the heap

```
auto p2 = make_unique<particle>();
```

- ▶ only then:
 - ▶ allocation of memory
 - ▶ execution of constructor
- ▶ allocation on the stack and heap behave differently, try it out!

Inheritance

- ▶ extend the concept described by a base class
- ▶ objects of the derived class can be used where an object of the base class is asked for

- ▶ avoid re-writing code

```
class particle_spin : public particle {  
    public:  
        particle_spin() : particle(), spin(0) {}  
  
    protected:  
        float spin;  
};
```

Virtual functions

```
class particle {  
    ...  
    virtual void decay();  
    ...  
};  
  
class particle_spin : public particle {  
    ...  
    virtual void decay();  
    ...  
};
```

Polymorphism

- ▶ code written for a particle should also work for a particle with spin

```
particle_spin p_spin();  
particle &p = p_spin;  
// ...  
p.decay();
```
- ▶ while you use a reference to a particle,
you (probably) want the method of the derived class to be called
- ▶ decision which method to call must happen at run-time!
↪ objects have vtable for virtual functions
- ▶ only overload virtual functions
(although C++ does not enforce this)

TFile class hierarchy

- ▶ TObject
- ▶ TNamed
- ▶ TDirectory
- ▶ TDirectoryFile
- ▶ TFile
- ▶ TNetFile, TMemFile, TXMLFile, TAlienFile, ...

have a look at:

<http://root.cern.ch/root/html/TFile.html>

Example

Try it out!

`examples/class`

Inheritance vs Member

- ▶ sometimes you can consider a class as a
 - ▶ parent class
 - ▶ member object
- ▶ with inheritance:
you can use the derived class in place of the parent class
- ▶ with member object:
you hide the details of the object
- ▶ think about what you want to achieve

Abstract base class

- ▶ you can write a class for which no actual realisation exists but which shall serve as the description of an interface
- ▶ achievable by requiring the implementation of a virtual function

```
class abstract {  
    public:  
        abstract();  
        virtual int get() const = 0;  
};
```

- ▶ only when all required virtual functions are implemented in a derived classes, instantiation is possible

override

What will happen?

```
class Foo {
public:
    virtual void print(const char* something) {
        std::cout << "Foo prints " << something << '\n';
    }
};

class Bar : public Foo {
public:
    virtual void print(const char* something) const {
        std::cout << "Bar prints " << something << '\n';
    }
};

int main ()
{
    Bar bar;
    Foo &foo = bar;
    foo.print("hi");
}
```

override

Help the compiler to find errors in inheritance with function overriding.

```
class Foo {
public:
    virtual void print(const char* something) {
        std::cout << "Foo prints " << something << '\n';
    }
};

class Bar : public Foo {
public:
    void print(const char* something) const override {
        std::cout << "Bar prints " << something << '\n';
    }
};

int main ()
{
    Bar bar;
    Foo &foo = bar;
    foo.print("hi");
}
```

Templates

- ▶ family of classes:
generic programming of a class unspecified data type

```
template <typename T>
class dummy {
public:
    dummy();
    const T& get_a();
protected:
    T a;
};
```

- ▶ compiler generates specializations for this class
when you use them

```
dummy<int> a;
dummy<float> b;
```

- ▶ more details and Standard Template Library (STL) later

Lecture VI

Selected c++11 features

Selected c++11 features

Discussed features

- ▶ `auto`
- ▶ Range based for loops
- ▶ `nullptr`
- ▶ Strongly typed enums
- ▶ `override` and `final`
- ▶ move semantics
- ▶ default and delete functions

What will not be covered

- ▶ Threading Support
- ▶ Static Assertions
- ▶ Variadic Templates
- ▶ `decltype`
- ▶ Alignment control (i.e., `alignof`, `alignas`, etc.)
- ▶ `static_assert` and type traits
- ▶ ...

examples: `git pull`

auto

auto leaves the type definition to the compiler. Very convenient in many situation. Can save lots of typing or typedef declarations.

```
auto i = 0; // not that useful
auto f = 0.f;

auto histogram = new TH1F("h", "h", 100,0,100); // more useful

std::vector<int> v{1,4,5};
for (std::vector<int>::iterator it = v.begin(); it != v.end(); ++it) ...
for (auto it = v.begin(); it != v.end(); ++it) ... //save typing!
```

Range based for loops

Simple way to loop over iterable types (stl container, root containers , c-arrays, ...).

```
std::vector<int> v{1,4,5};
for (const auto& val : v) std::cout << val << '\n';

float arr[]={4.,5.,6.};
for (const auto& val : arr) std::cout << val << '\n';

for (auto& val : arr) val*=val;
for (const auto& val : arr) std::cout << val << '\n';

for (auto val : arr) val*=val;
for (const auto& val : arr) std::cout << val << '\n';
```

`examples/cpp11/range_based.cpp`

Range based for loops

Can also be used with ROOT containers.

BUT: you have to know that a pointer to TObject is returned.

```
TClonesArray arr("TParticle");
for (int i=0; i<10; ++i) {
    TParticle& part = *static_cast<TParticle*>(arr.ConstructedAt(i));
    part.SetPdgCode(i);
}

for (auto o : arr) {
    TParticle& part = *static_cast<TParticle*>(o);
    std::cout << "Pdg code: " << part.GetPdgCode() << '\n';
}
```

`examples/cpp11/range_based.cpp`

nullptr

A specific *type* for null pointer. Before c++11 mainly 0, 0x0, NULL were used which is not type safe. Consider:

```
void print(int *i) { std::cout << "integer pointer: " << i << '\n'; }
void print(int i) { std::cout << "integer: " << i << '\n'; }

int main()
{
    print(0);
    print(NULL);
}
```

which will not compile

`examples/cpp11/nullptr_fail.cpp`

nullptr

nullptr solves this issue:

```
void print(int *i) { std::cout << "integer pointer: " << i << '\n'; }
void print(int i) { std::cout << "integer: " << i << '\n'; }

int main()
{
    print(0);
    print(nullptr);
}
```

will compile.

`examples/cpp11/nullptr.cpp`

Strongly typed enums

While names in normal enums cannot be the same

```
enum Animals {Bear, Cat, Chicken};  
enum Birds {Eagle, Duck, Chicken}; // error! Chicken has already been declared!
```

`examples/cpp11/enum_fail.cpp`

this is perfectly fine using strongly typed enums

```
enum class Fruits { Apple, Pear, Orange };  
enum class Colours { Blue, White, Orange }; // no problem!
```

`examples/cpp11/enum_strong.cpp`

Strongly typed enums

Also unintuitive that you could e.g. make bit operations between enums which are not strongly typed:

```
enum Animals {Bear, Cat};  
enum Birds {Eagle, Duck};  
  
bool b = Bear == Duck; // what?
```

Modern compilers should at least give a warning about this.

`examples/cpp11/enum_stupid.cpp`

Compilation fails with strongly typed enums

```
enum class Fruits { Apple, Pear, Orange };  
enum class Colours { Blue, White, Orange };  
  
bool b = Fruits::Orange == Colours::Orange; // what?
```

`examples/cpp11/enum_stupid_fail.cpp`

Strongly typed enums

You can specify the underlying integral type of C++11 enums:

```
enum class Foo : char { A, B, C };
```

In C++11 this works even for the 'normal' enums:

```
enum Bar : char { A, B, C};
```

override and final

Help the compiler to find errors in inheritance with function overriding.

```
class Foo {
public:
    virtual void print(const char* something) const final {
        std::cout << "Foo prints " << something << '\n';
    }
};

class Bar : public Foo {
public:
    void print(const char* something) const override {
        std::cout << "Bar prints " << something << '\n';
    }
};

int main ()
{
    Bar bar;
    Foo &foo = bar;
    foo.print("hi");
}
```

Use `final` if you don't intend a function to be overridden.

move semantics

C++11 has introduced the concept of rvalue references (specified with `&&`) to differentiate a reference to an lvalue or an rvalue. An lvalue is an object that has a name, while an rvalue is an object that does not have a name (a temporary object). The move semantics allow modifying rvalues (previously considered immutable and indistinguishable from `const T&` types).

```
class Foo {
public:
    Foo(int i) : val(i) {}
    std::vector<int> val;
};

Foo getBigFoo(i) { Foo foo(100000); return foo; }

int main() {
    Foo foo = getBigFoo();
}
```

The compiler implements a move operator

```
Foo(Foo&& other) ...
const Foo& operator= (Foo&& other) ...
```

move semantics

c++11 implements `std::move` which explicitly

```
std::string foo = "foo-string";
std::string bar = "bar-string";
std::vector<std::string> myvector;

myvector.push_back (foo);           // copies
myvector.push_back (std::move(bar)); // moves

std::cout << "foo is: " << foo << '\n';
std::cout << "bar is: " << bar << '\n';

std::cout << "myvector contains:";
for (const auto& x:myvector) std::cout << ' ' << x;
std::cout << '\n';
```

`examples/cpp11/move_string.cpp`

default and delete

The compiler will always try to implement e.g. a copy and assignment constructor as well as it's move counter parts. This can be forced as well as forbidden:

```
class Foo {  
    Foo::Foo() = default;  
    Foo::Foo(const Foo&) = delete;  
    Foo::Foo(Foo&&) = delete;  
    Foo& operator=(const Foo&) = default;  
    Foo& operator=(Foo&&) = delete;  
};
```

if you define 1 the other 5 will be automatically deleted! then you need to implement all 5.

Lambdas

A lambda is a nameless function with special properties:

- ▶ first class citizen - can be assigned to variables, passed to functions etc.
- ▶ can capture (i.e. copy or reference) variables from the outside scope irrespective of it's signature.

```
int x{4};  
int y{5};  
  
auto mylambda = [x,&y] (auto in, const auto& alsoin) {  
    return in + alsoin - x - y;  
};  
  
auto result = mylambda(3,7);
```

Lecture VII

Smart Pointers

pointers

- ▶ Pointers are a basic feature of C / C++
- ▶ Both one of the most powerfull and most dangerous features
- ▶ The majority of errors / bugs / security is related to memory management
- ▶ Use after free, buffer overflows are the most prominent cases
- ▶ (Semi-) Automatic memory management is desired, without loosing flexibility.

pointers

- Ownership problem

```
Particle* p = new Particle;  
Collection* c = new Collection;  
c->Add(p);
```

- Traditionally, containers need a flag whether they own or not?
- This is asking for trouble

pointers

- ▶ The solution in C++11: smart pointers

```
#include<memory>  
std::unique_ptr<int>  
std::shared_ptr<int>
```

- ▶ lifetime of managed resource managed by scoping (unlike raw pointers).
- ▶ The unique ptr is THE unique ptr pointing to the object, there cannot be a second one.
- ▶ Multiple shared pointers can point to an object, ownership is handled automatically, the last shared pointer that is destroyed also destroys the object.

pointers

- ▶ There are some limitations by design:
- ▶ Unique pointers cannot be copied or assigned (unique ownership!)

```
std::unique_ptr<int> p1(new int);  
std::unique_ptr<int> p2 = p1; //DOES NOT COMPILE!
```

- ▶ Operations like this require an explicit move (`std::move`) - The programmer should know what he does.

`examples/smart_pointers`

pointers in interfaces

- ▶ using raw pointers is still OK - just don't use "owning raw pointers"
- ▶ raw pointer only points at something which is guaranteed to exist (or use a reference).
- ▶ managed pointer signals ownership (transfer).

```
void function( int* look, std::unique_ptr<Particle> consume) {}
```

Lecture VIII

Standard Template Library

Template programming

Template programming is a different programming technique which allows to provide common functionality to many different data structures.

In this lecture we provide as much knowledge as it is needed to be able to work with the Standard Template Library (STL) functionality.

A template defines and implements a family of functions/classes with open data types.

```
template T class dummy {  
    public:  
        dummy();  
        const T& get_a();  
    protected:  
        T a;  
};
```

A template class or function can be used with any data type fulfilling the requirements. The compiler creates the specialized version for a specific data type.

Motivation - an example

Suppose there is an array of integers

```
const int size=10;
int array[10]={7,5,6,2,3,1,4,0,9,8};
```

An algorithm to *find* the position of an element can be

```
int *first=&array[0], *last=&array[10];
int value=7;
while (first != last && *first != value)
    ++first;
return first;
```

In a function it looks like

```
int* find(int* first, int* last, const int& value) {
    while (first != last && *first != value) ++first;
    return first;
}
```

Suppose, it's also needed for data type float

```
float* find(float* first, float* last, const float& value) {
    while (first != last && *first != value) ++first;
    return first;
}
```

Motivation - an example

Suppose there is an array of integers

```
const int size=10;
int array[10]={7,5,6,2,3,1,4,0,9,8};
```

An algorithm to *find* the position of an element can be

```
int *first=&array[0], *last=&array[10];
int value=7;
while (first != last && *first != value)
    ++first;
return first;
```

In a function it looks like

```
int* find(int* first, int* last, const int& value) {
    while (first != last && *first != value) ++first;
    return first;
}
```

Suppose, it's also needed for data type float

```
float* find(float* first, float* last, const float& value) {
    while (first != last && *first != value) ++first;
    return first;
}
```

Motivation - an example

Suppose there is an array of integers

```
const int size=10;
int array[10]={7,5,6,2,3,1,4,0,9,8};
```

An algorithm to *find* the position of an element can be

```
int *first=&array[0], *last=&array[10];
int value=7;
while (first != last && *first != value)
    ++first;
return first;
```

In a function it looks like

```
int* find(int* first, int* last, const int& value) {
    while (first != last && *first != value) ++first;
    return first;
}
```

Suppose, it's also needed for data type float

```
float* find(float* first, float* last, const float& value) {
    while (first != last && *first != value) ++first;
    return first;
}
```

Generalization

The two algorithms are identical, the functions only differ in the type
⇒ here the concept of templates helps to generalize the function

```
template<class T>
T* find(T* first, T* last, const T& value) {
    while (first != last && *first != value) ++first;
    return first;
}
```

Even more general, the type of the pointers does not need to be the same as the type of the value to search for

```
template<class Iterator, class T>
Iterator find(Iterator first, Iterator last, const T& value) {
    while (first != last && *first != value) ++first;
    return first;
}
```

The requirements to make this work are

- ▶ Iterator must support the prefix increment operator
- ▶ Iterator must support the !=-comparison operator
- ▶ dereferencing Iterator must give the type of the search value

Simplifying even further...

With C++14 we can even do:

```
auto find(auto first, auto last, const auto& value) {  
    while (first != last && *first != value) ++first;  
    return first;  
}
```

With the same requirements as before

Important to know

- ▶ the template class or function has to be implemented in the header file

A layout consisting of header file containing the function/class definition

```
template<class Iterator, class T>
Iterator find(Iterator first, Iterator last, const T& value);
```

and a source file with the implementation

```
template<class Iterator, class T>
Iterator find(Iterator first, Iterator last, const T& value) {
    while (first != last && *first != value) ++first;
    return first;
}
```

DOES NOT WORK!

The Standard Template Library

A set of C++ template classes to provide common programming data structures and functions:

- ▶ Container classes
<http://en.cppreference.com/w/cpp/container>
- ▶ iterator:
 - ▶ represent position in a container
 - ▶ declared to be associated with a single container class type
- ▶ algorithm:
 - ▶ routines to find, count, sort, search, ... elements in container classes

STL Containers

- ▶ Sequences:
 - ▶ vector: Dynamic array. Insert data at the end.
 - ▶ deque: Dynamic array. insertion/removal at beginning or end
 - ▶ list: linked list. Insert/remove anywhere.
- ▶ Associative Containers:
 - ▶ set: Collection of ordered data (no duplication). Fast search.
 - ▶ multiset: Collection of ordered data (duplication allowed). Fast search.
 - ▶ map: Collection of associative key-value pair with unique keys
 - ▶ multimap: Collection of associative key-value pair, duplicate keys allowed
- ▶ Container adapters:
 - ▶ stack LIFO
 - ▶ queue FIFO
 - ▶ priority_queue returns element with highest priority.
- ▶ String:
 - ▶ string: Character strings and manipulation
 - ▶ rope: String storage and manipulation
- ▶ bitset: intuitive method of storing and manipulating bits.

Example - the vector container

similar to an array, handles automatically its own storage requirements in case it grows

```
#include <vector>
using std::vector;

vector<int> v;
```

Basic operations:

push_back	Add element to end of collection.
pop_back	Remove element at end of collection
back	Get a reference to element at end of collection
front	Get a reference to element at end of collection
operator []	Access specified element

Note: the vector keeps the internally allocated memory also if the number of elements is reduced or all elements are erased.

Using a vector container

<code>empty</code>	determines if the collection is empty
<code>size</code>	number of elements in the collection
<code>capacity</code>	number of elements which can be added without growing the internal storage
<code>begin</code>	forward iterator pointing to the start of the collection
<code>end</code>	forward iterator pointing to one past the end of the collection
<code>rbegin</code>	backward iterator pointing to the end of the collection
<code>rend</code>	backward iterator pointing to one before the start of the collection
<code>clear</code>	erases all elements in a collection. Note: pointers must be deleted manually
<code>erase</code>	erase element or range of elements from a collection

STL containers vs. ROOT containers

ROOT also provides container classes, e.g. `TObjArray`, `TClonesArray`, `TList`.

Polymorphism is used to implement the ROOT collection classes

- ▶ every class needs to inherit from `TObject`
- ▶ collection classes only know about `TObject`
 - ⇒ every element return by access functions can only be of type `TObjArray`
 - ⇒ type casts are necessary

STL containers are type-safe because of the template approach

STL algorithms

- ▶ <https://en.cppreference.com/w/cpp/algorithm>
- ▶ expressive: say WHAT you mean to do, not HOW
- ▶ part of standard: in many compilers are allowed special optimizations.

e.g. instead of a (range-based) for loop:

```
std::vector<int> nums{3, 4, 2, 8, 15, 267};

int size{0};
std::for_each( nums.begin(), nums.end(), [&size] (auto& n) {
    ++n; ++size;
});
```

STL algorithms

- ▶ <https://en.cppreference.com/w/cpp/algorithm>
- ▶ expressive: say WHAT you mean to do, not HOW
- ▶ part of standard: in many compilers are allowed special optimizations.

or (a pretty generic) sort:

```
std::vector<int> nums{3, 4, 2, 8, 15, 267};

int ops{0};
std::sort( nums.begin(), nums.end(), [&ops] (const auto& a, const auto& b) {
    ++ops; return a < b;
});
```

<http://en.cppreference.com/w/cpp/algorithm>

`examples/template`

Lecture IX

More on gcc

Include files

- ▶ When dealing with larger code bases or external libraries, *header files* are used to define the interface of functions and classes
- ▶ During the compilation process the compiler needs to know where to look for header files
- ▶ This can be steered in two ways:
 - ▶ A compiler option
 - ▶ An environment variable
- ▶ A few system directories are included by default like
 - ▶ `/usr/include`
 - ▶ `/usr/local/include`

Include files - search path

compiler flag

- ▶ Search paths can be added using the `-I` compiler option
- ▶ One statement is needed per path
- ▶ No space between `-I` and the path
- ▶ With GCC, you can use `-isystem` instead of `-I` to suppress warning in include files.

```
g++ -I. -I/path/one -I/path/two ...
```

environment variable

- ▶ `C_INCLUDE_PATH`
- ▶ `CPLUS_INCLUDE_PATH`
- ▶ colon separated list of paths

```
export CPLUS_INCLUDE_PATH=./path/one:/path/two
```

Include files - search path

compiler flag

- ▶ Search paths can be added using the `-I` compiler option
- ▶ One statement is needed per path
- ▶ No space between `-I` and the path
- ▶ With GCC, you can use `-isystem` instead of `-I` to suppress warning in include files.

```
g++ -I. -I/path/one -I/path/two ...
```

environment variable

- ▶ `C_INCLUDE_PATH`
- ▶ `CPLUS_INCLUDE_PATH`
- ▶ colon separated list of paths

```
export CPLUS_INCLUDE_PATH=./path/one:/path/two
```

Include files - search path - example

- ▶ Create a subdirectory 'header'
- ▶ Move the file *hello_fn.h* there
- ▶ Try to compile the code again

⇒ Try it!

Try both possibilities to declare a search path:

```
g++ -Wall -Iheader main.cpp hello_fn.cpp -o hello_world
```

```
export CPLUS_INCLUDE_PATH=header  
g++ -Wall main.cpp hello_fn.cpp -o hello_world
```

Include files - search path - example

- ▶ Create a subdirectory 'header'
- ▶ Move the file *hello_fn.h* there
- ▶ Try to compile the code again

⇒ Try it!

Try both possibilities to declare a search path:

```
g++ -Wall -Iheader main.cpp hello_fn.cpp -o hello_world
```

```
export CPLUS_INCLUDE_PATH=header  
g++ -Wall main.cpp hello_fn.cpp -o hello_world
```

Libraries

- ▶ Object files can be combined in so-called *libraries*
- ▶ Two different kinds of libraries exist
 - ▶ Static libraries (ending on .a)
 - ▶ Objects needed for the code execution are copied into the executable
 - ▶ Increases the code size
 - ▶ If several programs use the same static libraries, they all load the same code into memory during execution time
 - ▶ Dynamic libraries (ending on .so)
 - ▶ Are linked against the program during compilation time
 - ▶ Are loaded into memory during the program execution
 - ▶ Does not increase the code size
 - ▶ The code in memory can be shared among all programs requiring it

Libraries

- ▶ Object files can be combined in so-called *libraries*
- ▶ Two different kinds of libraries exist
 - ▶ Static libraries (ending on `.a`)
 - ▶ Objects needed for the code execution are copied into the executable
 - ▶ Increases the code size
 - ▶ If several programs use the same static libraries, they all load the same code into memory during execution time
 - ▶ Dynamic libraries (ending on `.so`)
 - ▶ Are linked against the program during compilation time
 - ▶ Are loaded into memory during the program execution
 - ▶ Does not increase the code size
 - ▶ The code in memory can be shared among all programs requiring it

Libraries

- ▶ Object files can be combined in so-called *libraries*
- ▶ Two different kinds of libraries exist
 - ▶ Static libraries (ending on `.a`)
 - ▶ Objects needed for the code execution are copied into the executable
 - ▶ Increases the code size
 - ▶ If several programs use the same static libraries, they all load the same code into memory during execution time
 - ▶ Dynamic libraries (ending on `.so`)
 - ▶ Are linked against the program during compilation time
 - ▶ Are loaded into memory during the program execution
 - ▶ Does not increase the code size
 - ▶ The code in memory can be shared among all programs requiring it

Libraries

- ▶ As for include paths, g++ also needs to know where to search for the libraries when creating an executable
- ▶ This can be steered in two ways
 - ▶ A compiler option
 - ▶ An environment variable
- ▶ A few system directories are included by default like
 - ▶ /usr/lib
 - ▶ /usr/local/lib

Libraries - search paths

compiler flag

- ▶ Search paths can be added using the `-L` compiler option
- ▶ One statement is needed per path

```
g++ -L/path/one -L/path/two ...
```

environment variable

- ▶ `LIBRARY_PATH` - static libs
- ▶ `LD_LIBRARY_PATH` - dynamic libs
- ▶ colon separated list of paths

```
export LIBRARY_PATH=/path/one:/path/two
```

Libraries - search paths

compiler flag

- ▶ Search paths can be added using the `-L` compiler option
- ▶ One statement is needed per path

```
g++ -L/path/one -L/path/two ...
```

environment variable

- ▶ `LIBRARY_PATH` - static libs
- ▶ `LD_LIBRARY_PATH` - dynamic libs
- ▶ colon separated list of paths

```
export LIBRARY_PATH=/path/one:/path/two
```

Libraries - dynamic libraries

- ▶ Dynamic libraries are not compiled into the code
- ▶ They need to be loaded during the run time, when the program is executed
- ▶ For this the *dynamic linker* needs to know where to search for the libraries
- ▶ If dynamic libraries don't reside in the 'default' paths of the system it has to be declared using the `LD_LIBRARY_PATH` environment variable

Libraries - an example

create objects

```
g++ -fPIC -c hello_fn.cpp main.cpp
```

NOTE: -fPIC is required to prepare for dynamic libraries!

link function object into dynamic library

```
g++ -shared hello_fn.o -o libHello.so
```

create executable and bind library

```
g++ -o hello_dynamic main.cpp -L. -lHello
```

Libraries - an example

create objects

```
g++ -fPIC -c hello_fn.cpp main.cpp
```

NOTE: -fPIC is required to prepare for dynamic libraries!

link function object into dynamic library

```
g++ -shared hello_fn.o -o libHello.so
```

create executable and bind library

```
g++ -o hello_dynamic main.cpp -L. -lHello
```

Libraries - an example

create objects

```
g++ -fPIC -c hello_fn.cpp main.cpp
```

NOTE: -fPIC is required to prepare for dynamic libraries!

link function object into dynamic library

```
g++ -shared hello_fn.o -o libHello.so
```

create executable and bind library

```
g++ -o hello_dynamic main.cpp -L. -lHello
```

Warning options

-Wall

- ▶ Warnings for most common errors
 - ▶ -Wcomment, -Wformat, -Wunused, -Wimplicit, -Wreturn-type, . . .
 - ▶ Can also be activated individually
- ▶ Includes many sub-switches
- ▶ Always use at least this one
- ▶ Consider using other warning options

Warning options

-W

- ▶ A general option similar to -Wall
- ▶ Check non-void functions return a value

```
int myFunction() { float x=3.; }
```

- ▶ Check comparison between signed/unsigned

```
int i = 8;  
unsigned int j = 8;  
if ( i == j ) {}
```

- ▶ ...
- ▶ In general used with -Wall

Warning options

- ▶ `-Wconversion` check implicit type conversion

```
unsigned int x = -1;
```

- ▶ `-Wshadow` check if a variable declaration can shadow another one

```
int x=1; {int x=5;}
```

- ▶ `-Wwrite-strings` don't allow non const c-strings

- ▶ ...

- ▶ →

Compiler optimisation

- ▶ GCC is an optimising compiler
- ▶ Optimisation could be
 - ▶ faster execution
 - ▶ smaller executable (memory stamp)
 - ▶ → speed-space tradeoff

Compiler optimisation levels

- ▶ `-O0` or none (default)
No optimisation, compilation in most straight-forward way, best for debugging
- ▶ `-O1` or `-O`
 - ▶ Most optimisations without speed-space tradeoff
 - ▶ Should result in smaller executable AND faster code
 - ▶ Might also compile faster
- ▶ `-O2`
 - ▶ More optimisation than `-O1`, still without speed-space tradeoff
 - ▶ Should result in faster code without and increase in size
 - ▶ Compilation takes longer and needs more memory
- ▶ `-O3`
 - ▶ Even more than `-O1`, `-O2`
 - ▶ Should result in faster code, might increase the executable size
 - ▶ Compilation takes longer and needs more memory

Compiler optimisation levels

- ▶ `-ffast-math`
 - ▶ Floating point operations on the CPU are non-associative
 $(x*(y+z) \neq x*y + x*z)$
 - ▶ Therefore the compiler usually does not perform math simplifications of your code
 - ▶ **-ffast-math** tells enables to compiler to do so but the numerical result might be different than without `-O2`
 - ▶ Fast math also disables some error treatment and assumes that basically all of your calculations are well defined.
 - ▶ Can really improve the speed

[link to discussion on stackoverflow](#)

Compiler optimisation levels

- ▶ Unroll loops: `-funroll-loops`
 - ▶ There is a trade-off: Less control-flow and fewer jumps in the code.
 - ▶ Larger code, thus worse cache utilization.
 - ▶ The compiler cannot always determine the optimal unroll level.
 - ▶ One can try manual unrolling (see example).
- ▶ Similar: `-finline-functions`.
- ▶ Disabled with `-fno-unroll-loops -fno-inline-functions`.

```
int x[3];  
for (int i=0; i<3;++i){  
    x[i]=i*i;  
}
```

```
int x[3];  
x[0]=0;  
x[1]=1;  
x[2]=4;
```

- ▶ `-Os`
 - ▶ Optimise for size (Optimizes also cache, Windows is compiled like this)
 - ▶ Use most optimisations also used in `-O2` (that don't increase the size)

[examples/performance/09_unroll/](#)

⇒ Try it!

List of some important compiler options

- ▶ Select the correct CPU architecture
 - ▶ New processors provide new more powerful instructions.
 - ▶ Compilers generate compatible code for all architectures.
 - ▶ One can enable additional sets of instructions with `-msse`, ..., `-msse41`, `-m3dnow`, `-mavx`.
 - ▶ Use `-march=ARCHITECTURE` flag to select target architecture (with instruction set).
 - ▶ ARCHITECTURE can be e.g. `i386`, `pentium`, `nocona`, `opteron`, **native**.
- ▶ `-fomit-frame-pointer`
 - ▶ Enabled with `-O2`, makes one additional CPU register available for optimizations.
 - ▶ Complicates access to stack frame, sometimes prevents creation of backtraces in GDB, valgrind, perf.
 - ▶ Can be disabled for debugging / profiling:
`-fno-omit-frame-pointer`.

List of some important compiler options

- ▶ `-o <executable name>` name the executable default is `a.out`
- ▶ `-g -ggdb` add debugging symbols
- ▶ `-O<level>` code optimization with different levels
- ▶ `-W<xxx>` compiler warnings
- ▶ `-c` create objects instead of an executable
- ▶ `-I<path>` add search path for include file
- ▶ `-L<path>` add search path for libraries
- ▶ `-l<LIB>` link `lib<LIB>.so` into the binary
- ▶ `-ansi` disable GNU C language extension that conflict with the ANSI/ISO C standard
- ▶ `-pedantic` used with `-ansi` ALL GNU C language extensions are disabled
- ▶ `-std=...` select a special c-standard (e.g. C99, `c++11`, `gnu++11`, `c++14`)

Remember

- ▶ Never compile code without gcc warnings enabled
- ▶ Take ALL warnings seriously
- ▶ Fix ALL warnings

Godbolt - Playground

A demonstration with godbolt.org

Lecture X

ROOT - Intro / Libs / IO / Trees

ROOT

Some info about ROOT

- ▶ root.cern.ch: A modular scientific (C++) software toolkit. It provides all the functionalities needed to deal with big data processing, statistical analysis, visualisation and storage.
- ▶ Used by most high energy physics experiments (e.g. at CERN, GSI, BNL, Fermilab, neutrino experiments, ...)
- ▶ Allows for simple code prototyping with a just-in-time compiler Cling (ROOT 6)
- ▶ Allows for C++ introspection and automatic serialization of any C++ class

ROOT : Our interest/scope

ROOT is vast and goes beyond the goal of this course. The features that we want to highlight here

- ▶ ROOT as a library: How to use some of its functionality
- ▶ ROOT as IO/serialization mechanism and data inspector
 - ▶ understand creation of dictionaries
 - ▶ understand TTree storage
 - ▶ understand data inspection from a TTree / TBrowser

ROOT as a library

ROOT has lot's of service classes which one could use (in your project) to get quickly started. The usage is the normal **include** / **use** / **link**.

```
#include <TRandom3.h>    // include a ROOT random number generator
#include <iostream>

int main() {
    TRandom3 generator;
    // get a poissonian distributed random number around 5
    std::cout << generator.Poisson(5) << std::endl;
}
```

`root-config` can be used to get include path and libraries:

```
g++ -O2 -I`root-config --incdir` -c main.cxx
g++ main.o `root-config --libs` -o main.exe
```

`examples/rootaslib`

Bonus: ROOT and cmake

- ▶ A minimal example how to add ROOT include paths and libraries in cmake
- ▶ more docu here
root.cern.ch/how/integrate-root-my-project-cmake

```
cmake_minimum_required(VERSION 3.0 FATAL_ERROR)
project(myproject)
find_package(ROOT REQUIRED)
include_directories(${ROOT_INCLUDE_DIRS})

#---Create the main program using the library
add_executable(main.exe main.cxx)
target_link_libraries(main.exe ${ROOT_LIBRARIES})
```

examples/rootaslib

ROOT as a library

What could be useful at first for your project

- ▶ random numbers
- ▶ random numbers from arbitrary distributions using TF1 class
- ▶ 3-body decay simulation provided by TGenPhasePhase

However, sometimes these implementations may be

- ▶ too generic hence not as performant as specialized code
- ▶ not thread-safe preventing parallelisation
- ▶ (not compilable on GP-GPU etc)
- ▶ superceeded by modern C++11 constructs

so that one needs to refactor (later on).

- ▶ It is generally no longer advised to use ROOT containers such as TList, TArray, TMatrix
- ▶ It is also no longer necessary to derive any class from TObject

Introduction to ROOT serialization and TTrees

The killer-feature of ROOT is the ability to serialize **any** C++ class, i.e., write it to disc in binary form and reinstantiate the object later on from disc, at almost no developer cost.

```
class Position {  
public:  
    Position() = default;  
  
    float getR2() const;  
  
private:  
    float x = 0;  
    float y = 0;  
    float z = 0;  
};
```

serialize

read

visualize
analyze

ROOT serialization example

Example writing a user object to a TFile and read it back in:

```
// In Foo.h
struct Foo {
    std::string name;
    float x = 0;
    double y = 0;
};
```

```
// in the main program
int main() {
    TFile file("outfile.root", "RECREATE");
    Foo f("hello", 1.5, 2.); // make a Foo instance

    // write to file using some key name
    file.WriteObjectAny((void*)f, TClass::GetClass(typeid(Foo)), "key");

    // read back from file
    Foo* anotherfoo = nullptr;
    file.GetObject("key", anotherfoo);
    return 0;
}
```

ROOT dictionaries

- ▶ in order for this to work we only need to create a dictionary for every class we want to write out
- ▶ The dictionary is an autogenerated shared library containing information about your class
- ▶ This needs a LinkDef.h file mentioning your class:

```
#ifndef __CLING__  
#pragma link off all classes;  
#pragma link off all functions;  
#pragma link off all globals;  
  
#pragma link C++ class Foo+;  
#endif
```

- ▶ the dictionary is created in 2 steps

```
rootcling Foo.h LinkDef.h -f FooDict.cxx  
g++ -shared -o libFooDict.so `root-config --ldflags` -O2 FooDict.cxx
```

- ▶ See code example for easy ways how this is done with cmake

[examples/basicrootio/write_read/](#)

Serialization/storage with TTrees

- ▶ **TTree** (or TBranch) is a **special container** used to serialize **many instances** of your class to disc
- ▶ Serialization is done very efficiently, i.e. using compression
- ▶ Serialization is done for each data member separately (SoA) - columnar data format
- ▶ This allows access to single data members without the need to read all data
- ▶ Easy way to quickly analyse and visualize data stored (TTree::Draw())

`examples/basicrootio/trees_userclass/`

`examples/trees`

A simple example.C

```
TF1 fpt("fpt", "<mycomplex function>", 0.1, 100);

TFile f("output.root", "recreate");
TTree t("tree", "tree");
Float_t z=0.;
TLorentzVector *v=new TLorentzVector;

t.Branch("z", &z);
t.Branch("particle", &v);

for (Int_t ientry=0; ientry<10000; ++ientry) {
    z=gRandom->Gaus(0,5);

    Double_t phi = gRandom->Uniform(0.0, TMath::TwoPi());
    Double_t eta = gRandom->Uniform(-1, 1);
    Double_t pt  = fpt.GetRandom();
    v->SetPtEtaPhiM(pt, eta, phi, .14);

    t.Fill();
}

f.Write();
f.Close();
delete v;
```

Short discussion about the program

- ▶ Trees can be associated to a file:
 - ▶ First open a file in write mode
 - ▶ Then create the tree
 - ▶ This ensures automatic saving of the data to file and frees the memory
- ▶ It is simple to add branches for primitive type and also complex classes (see user example)

Filling a tree

- ▶ Fill all the data members you associated with the branches
- ▶ Calling the Fill function then dumps all the values of the objects into the tree structure

Accessing the data (read.C)

```
TH1F *hPt=new TH1F("hPt","p_{T}; p_{T} (GeV/c)", 100,0,10);
TH1F *hZ=new TH1F("hZ","z; z (cm)", 100,0,10);
TFile f(filename);
gROOT->cd();

TTree *t=(TTree*)f.Get("tree");

Float_t z=0.;
TLorentzVector *v=nullptr;

t->SetBranchAddress("z",&z);
t->SetBranchAddress("particle",&v);

for (Int_t iev=0; iev<t->GetEntries(); ++iev) {
    t->GetEntry(iev);
    hPt->Fill(v->Pt());
    hZ->Fill(z);
}

delete v;
```

Visualizing data in TTrees

- ▶ data in TTrees can be inspected in the `TBrowser`
- ▶ data in TTrees can be inspected in the `TTreeView`
- ▶ using directly the underlying `TTree::Draw(what, cut)` interface
 - ▶ goes over all data described in `what` under certain selection criteria `cut`
 - ▶ produces a histogram presenting the selected data or some other higher dimensional plot
 - ▶ see <https://root.cern.ch/doc/master/classTTree.html>

More on Branches

- ▶ There are many different ways to create a branch, have a look at the documentation
- ▶ It even allows full C++ incl. STL, class does not need to derive from TObject

```
TBranch* Branch(const char* name, void** obj,  
                Int_t bufsize = 32000)
```

Two important things

- ▶ bufsize is the size of the branch buffer in memory before it is written to file
 - ▶ Can be used to optimize the I/O
 - ▶ Too small numbers might result in many writes of small data chunks
 - ▶ Too large numbers might fill the memory too quickly
- ▶ If complex objects contain 'sub-objects' they get assigned their own branch

Your exercise

- ▶ Understand the examples
- ▶ Try writing your own class to disc / TTree
- ▶ Play around with TTree::Draw, reading of data, ...
- ▶ Play around with the TBuffer buffer size, check execution time using a simple timer (ROOT offers TStopWatch)

Lecture XI

Code documentation using doxygen

Code documentation

What you have to keep in mind:

- ▶ You or somebody else wants to understand your code, especially after some time when it needs to be extended or a bug needs to be fixed
- ▶ You should use a consistent documentation style
- ▶ Better add more comments

A short introduction to get you started with **doxygen**

For further reading [doxygen](#) [dokuo](#)

Running Doxygen

To generate a manual for your project you typically need to follow these steps

1. document your source code with special documentation blocks
2. generate a configuration file by calling doxygen with the -g option:

```
doxygen -g <config_file>
```

3. edit the configuration file to match the project
4. run doxygen to generate the documentation

```
doxygen <config_file>
```

Sample session:

In the examples/tooling directory:

1. fetch the latest version of the example

```
git pull
```

2. Generate the documentation

```
doxygen -g doxygen.conf
```

Doxygen - The configuration file

The operation can be tuned by many options in the config file, all of them are described in the generated template. The name of the project is likely to be adjusted.

```
# The PROJECT_NAME tag is a single word (or sequence of words) that should  
# identify the project. Note that if you do not use Doxywizard you need  
# to put quotes around the project name if it contains spaces.
```

```
PROJECT_NAME           = "A simple test project"
```

Also the input, i.e. source and header files, can be adjusted,

```
#-----  
# configuration options related to the input files  
#-----  
# The INPUT tag can be used to specify the files and/or directories that contain  
# documented source files. You may enter file names like "myfile.cpp" or  
# directories like "/usr/src/myproject". Separate the files or directories  
# with spaces.
```

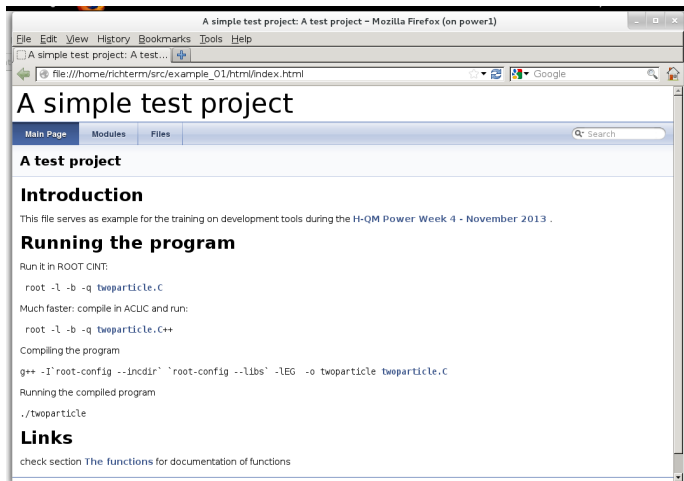

```
INPUT                   =
```

```
# If the value of the INPUT tag contains directories, you can use the  
# FILE_PATTERNS tag to specify one or more wildcard pattern (like *.cpp  
# and *.h) to filter out the source-files in the directories. If left  
# blank the following patterns are tested:  
# *.c *.cc *.cxx *.cpp *.c++ *.d *.java *.ii *.ixx *.ipp *.i++ *.inl *.h *.hh  
# *.hxx *.hpp *.h++ *.idl *.odl *.cs *.php *.php3 *.inc *.m *.mm *.dox *.py  
# *.f90 *.f *.for *.vhd *.vhdl
```

Build the documentation and open it

```
richterm@power1 ~/src/example_01 $ doxygen doxygen.conf
```

```
firefox file://$PWD/html/index.html
```

Doxygen - Special comment blocks

C or C++ style comment block with some additional markings parsed by doxygen

1. Javadoc style: C-style comment block starting with two `*`'s

```
/**
 * ... text ...
 */
```

- ## 2. Qt style

```

/*!
 * ... text ...
 */

```

3. block of at least two C++ comment lines, where each line starts with an additional slash or an exclamation mark

```

///
/// ... text ...
///

//!
//! ... text ...
//!

```

twoparticle.C documentation - copyright notice

The code should have a copyright information containing

- ▶ the author name/group
- ▶ terms of usage

```

Lecture XII

Libraries

Command-line parameters

- ▶ common and frequent problem:
parsing of command line options
- ▶ based on array of strings passed from OS
- ▶ different approaches:
 - ▶ write your own parsing
 - ▶ getopt
 - ▶ boost program options
 - ▶ ...
- ▶ usually you want to provide a consistent help
(I forget the options I implemented yesterday)

main prototype

- ▶ every executable needs a main function as an entry point
- ▶ it can have
 - ▶ no arguments:
`int main()`
 - ▶ two arguments:
`int main(int argc, char *argv[])`
(or equivalent)
 - ▶ argc contains the number of arguments
 - ▶ first argument is the name of the executable
 - ▶ argv is an array of C-strings,
last string is 0

getopt

- ▶ C library function
very wide-spread, e.g. also on embedded systems
- ▶ documentation must be synchronised manually
- ▶ let's look at a short example,
then try and get it running

`examples/getopt`

getopt – example

```
int main(int argc, char *argv[]) {
    static struct option long_options[] = {
        {"file", required_argument, 0, 'f'},
        {0, 0, 0, 0}
    };
    char c; int option_index = 0;
    while (1) {
        c = getopt_long(argc, argv, "f:", long_options, &option_index);
        if (c == -1)
            break;
        switch (c) {
            case 'f':
                // remember filename
                break;
            default:
                // unrecognized option
        }
    }
}
```

boost program options

- ▶ boost is a collection of C++ libraries for various purposes, e.g. CRC calculation, configuration file reading, and program options
- ▶ boost makes extensive use of templating and meta programming, fine with recent compilers, problematic with old ones
- ▶ limited to C++
- ▶ far more features and more C++-like formulation
- ▶ let's look at a short example, then try and get it running

`examples/boost_option`

boost program options – example

```
#include <iostream>
#include <boost/bind.hpp>
#include <boost/program_options.hpp>
namespace po = boost::program_options;
void show_help(po::options_description desc)
{
    std::cout << "Hope it helps:" << std::endl;
    std::cout << desc;
}

int main(int argc, const char **argv) {
    // Declare the supported options.
    po::options_description desc("Allowed options");
    desc.add_options()
        ("help", "produce help message")
        ("compression", po::value<int>(), "set compression level")
        ;

    po::variables_map vm;
    po::store(po::parse_command_line(argc, argv, desc), vm);
    po::notify(vm);
    if (vm.count("help")) {
        std::cout << desc << "\n";
        return 1;
    }
    if (vm.count("compression")) {
        std::cout << "Compression level was set to "
        << vm["compression"].as<int>() << "\n";
    } else {
        std::cout << "Compression level was not set.\n";
    }
}
```
